Statement of Purpose

Rhea Choudhary
[University name]

Research interests. I am applying to pursue a PhD in [Program name]at [University name], where I intend to study questions at the intersection of public, labour and health economics. My specific research agenda asks how large-scale government programs can better achieve their desired policy objectives, and the externalities created by such programs in the pursuit of these goals.

So far, I have begun to tackle this research agenda in three key ways: in my undergraduate Honours thesis, my predoctoral position and in independent research. In my Honours thesis published as a central bank working paper, I evaluated the effects of unconventional monetary policy on financial stability in an emerging market context. Since my undergraduate studies, my interests have shifted and I now have been pursuing this research agenda through topics in applied microeconomics. In my pre-doctoral research, I am examining how the introduction of Australia's National Disability Insurance Scheme (NDIS) changed the labour market composition and returns to disability work, and in my independent research, I have been exploring the efficacy of large-scale supply-side education policies on improving individual employment outcomes as well as labour market shortages. Methodologically, I seek to use microdata, particularly Australian microdata which I have used as part of my pre-doctoral research, with theoretical models to imbue greater intuition to empirical findings.

Pre-doctoral and professional experience. I have been broadening my research toolkit working for Professor Manasi Deshpande as a pre-doctoral researcher. Our project examines the labour supply effects of NDIS, which is a first-of-its-kind disability support program, where the federal government provides a budget to individuals with disabilities based on their needs, which can be spent in the private market on services like personal care, household tasks and physical/behavioural therapy. We have been exploiting the staggered rollout of NDIS to examine how this large-scale government program causally changed employment and earnings among new and incumbent disability workers as well as related professions such as nursing and therapy. We find that the marginal entrant induced by NDIS to enter disability work are low-income, lower-skilled women who were previously not working, who obtain modest earnings increases from entry. We are now conducting analysis that attributes the returns to NDIS that flow to workers, firms and households, and intend to examine whether and how large labour market entry into disability care in response to this demand shock affected downstream care for people with a disability. Through this research I have gained significant experience working with large administrative datasets and independently applying an array of causal inference methods such as staggered rollout event studies, DiD and shift-share instruments, as well as using LASSO to define a base population of interest. I have also gained valuable skills in how to carefully implement these econometric methods in ways that ensure credible identification.

Prior to my pre-doctoral position, I worked at the Reserve Bank of Australia, Australia's equivalent of the Federal Reserve. In this role, I led an array of analytical research, most recently running a contingent valuation experiment in a large-scale population representative survey, which is in the process of becoming a central bank working paper. Overall, I believe my pre-doctoral and professional experience have instilled important skills to prepare me for graduate school and PhD research, such as creative problem-solving, methodical thinking through complex questions, and

conducting economic research deliberately and credibly.

Future research. While auditing Professor Deshpande's course 'Empirical Analysis of Social Insurance' in the spring, I became interested in how social transfers target cohorts when need is unobservable (Akerlof, 1978; Nichols and Zeckhauser, 1982), and the challenge in balancing efficient targeting with creating barriers to take-up among intended cohorts (Deshpande and Li, 2019). I was also curious about how I could apply learnings from this literature in social insurance to government programs more broadly. An Australian education policy called 'Free TAFE', where from 2019-2022 the state of Victoria offered a free vocational education for certain courses that were deemed to have labour shortages, could be an interesting case-study to study this topic.[1] This policy is unique in that eligibility is governed by what courses are available rather than at the recipient level (e.g., by means-testing or employment history). At first glance, it is unclear which approach is more effective. On the one hand, course-level targeting could achieve two goals simultaneously: like other supply-side policies, it reduces education costs that can deter low-income, low-education individuals with high marginal returns from enrollment, and attempts to maximise the likelihood this education translates to employment by prioritising courses with labour shortages. It is also plausibly easier to implement, given labour shortage sectors is more observable than recipients' underlying need. However, without individual-based targeting, such programs rely on efficient self-sorting and its possible high-return cohorts (such as low-skilled, low-education individuals) could be crowded out of program spots by individuals with low opportunity costs to enrolment but potentially observably lower need or lower marginal returns to the course.

Therefore, in this research, I ask two questions: firstly, whether and how targeting on the subsidised good produces different outcomes from participant-side targeting, and more generally, whether preferentially subsidised training is a legitimate lever for upskilling individuals into growth sectors when implemented at scale. I do this by comparing outcomes among Victorian residents, where free TAFE was accessible, to other states where this program had not yet been implemented. I have been using linked unit-level administrative data from the Australian Bureau of Statistics, which allow me to observe individuals' prior education history, socio-economic background, parental income, health, and employment outcomes over time.

To answer my first question on targeting, I compare whether the program changed the composition of enrolments in these courses across age, gender, labour force status at enrolment, and highest education level. Inspired by the targeting efficiency work in Deshpande and Li (2019) and complier analysis from Mountjoy (2022), I intend to explore how well this course-based targeting measure fared in inducing likely 'target cohorts' to enter the program (e.g., low-skilled, low-income cohorts), dissuaded individuals with low marginal returns to this education from enrolling, and how much of the enrolment effect comes from inframarginal enrolees.

On my second research question, I am interested in whether wage premia in targeted sectors changed if supply of skilled workers increased, and whether provision shifts the composition of the local training market. In my work thus-far, I find that low-skilled women have the strongest enrolment first-stage, and so as extensions I would like to consider how outcomes like marriage and fertility changed in response to this program.

[1] Examples include disability care, nursing, construction, and early childhood care. From 2023 onwards, this program was phased in by other states and received Commonwealth funding.
